Q1. How many users were assigned to Group A and Group B?

We need this query to verify how many users were assigned to the control group (A) and treatment group (B). It helps check whether the experiment has the expected group distribution before comparing conversion rates and evaluating the redesigned checkout page.

Q2. What is the purchase conversion rate for Group A versus Group B?

we need this query to compare the percentage of users who made a purchase in Group A (existing checkout page) versus Group B (redesigned checkout page). It helps us identify which page converts more users and whether the redesigned page performs better.

3. What is the absolute and relative conversion uplift of Group B compared with Group A?

This query measures how much Group B's conversion rate increased or decreased compared with Group A, helping us understand the impact of the redesigned checkout page.

4. Which checkout page generates higher total revenue and revenue per user?

This query compares total revenue, revenue per user, and average order value for both groups to identify which checkout page generates better business results.

5. Which device type has the highest purchase conversion rate in Group A and Group B?

This query compares conversion rates across desktop, mobile, and tablet users to identify which devices perform best with each checkout page.

6. Which traffic source has the highest purchase conversion rate in Group A and Group B?

This query compares conversion rates across different traffic sources to understand how each checkout page performs for users arriving through different channels.

7. How many users are from each country?

This query counts users from each country to understand the geographical distribution of users and identify major markets.

8. How many users purchased and how many did not purchase?

This query counts users who purchased and those who did not, helping us understand overall customer purchasing behavior.

9. What is the total revenue generated by each experiment group?

This query calculates total revenue for Group A and Group B to compare the overall revenue generated by each checkout page.

10. Which experiment group has a higher average checkout completion time among users who purchased?
This query compares the average checkout completion time among purchasers to determine which checkout page provides a faster purchasing experience.
